Equations and Backgrounds

The semilinear elliptic equation with **singular nonlinearity** is given by

$$\Delta u = u^{-p} + f, \quad u \geq 0 \quad \text{in } \Omega \subset \mathbb{R}^n, \quad n \geq 2, \quad p \geq 0, \quad (\text{SN})$$

where Ω is a domain and $f \in L^1_{\text{loc}}(\Omega)$.

Some **mathematical** and **physical** backgrounds are as follows.

- ① $p = 0$: $\Delta u = \chi_{\{u>0\}}$, **obstacle problem**, **free boundary problem**.
- ② $p > 0$:
 - $p > 1$: **Thin film** theory.
 - $p = 2$: Simplified micro-electromechanical system (**MEMS**).
 - $p = 1$: Singular **minimal hypersurfaces** with symmetry.

Example

For $p = 2$, $n = 1$ and $f \equiv 0$, an easy derivation of the model is the dynamical analysis of two **homopolar** charges under the Coulomb force.

Problems Setting: Motivation

Consider the regularity theory for solutions of (SN) with $p > 0$.

If $u \in C^0$ and $f \in C^\infty$, then

$$x \in \{u > 0\} \Rightarrow \exists r > 0, \text{ s.t. } \inf_{B_r(x)} u > 0 \Rightarrow u \in C^\infty(B_r(x)).$$

As a result, $\{u = 0\}$ is the **singular set** of u , and $\{u > 0\}$ is the **regular set**.

For the thin film theory, $\{u = 0\}$ refers to the **rupture** phenomenon.

Question

How large are **rupture sets** for solutions of (SN) with $p > 0$? What **assumptions** will we have to obtain such results?

For $0 < p < 1$, solutions behave like those for case $p = 0$. There are almost complete results even for **two phases** (Tavares and Terracini, JMPA 2019). We mainly consider the case $p > 1$, which is very different from $0 < p < 1$.

Problems Setting: Different Solutions

For (SN) with $p > 1$, some definitions are as below.

- 1 **Weak solution:** $u \in (H_{\text{loc}}^1 \cap L_{\text{loc}}^{-p})(\Omega)$, (SN) is satisfied in the sense of distribution.
- 2 **Finite energy solution:** $u \in (C_{\text{loc}}^0 \cap H_{\text{loc}}^1 \cap L_{\text{loc}}^{1-p})(\Omega)$, and we have (SN) in $\{u > 0\}$, in the sense of distribution.
- 3 **Stationary solution:** weak solution + stationary condition, namely,
 $\forall Y \in C_0^\infty(\Omega, \mathbb{R}^n)$,

$$\int_{\Omega} \left[\left(\frac{|\nabla u|^2}{2} - \frac{u^{1-p}}{p-1} \right) \operatorname{div} Y - DY(\nabla u, \nabla u) - f(Y \cdot \nabla u) \right] = 0. \quad (\text{SC})$$

The corresponding functional of (SN) is

$$\mathcal{F}_f(u, \Omega) := \int_{\Omega} \left(\frac{|\nabla u|^2}{2} - \frac{u^{1-p}}{p-1} + fu \right).$$

Then

$$(\text{SC}) \Leftrightarrow \left. \frac{d}{dt} \right|_{t=0} \mathcal{F}_f(u(\cdot + tY(\cdot)), \Omega) = 0.$$

Problems Setting: Present Results

Let d_u be the [Hausdorff dimension](#) of the rupture set $\{u = 0\}$.

① Weak solution:

- $d_u \leq n - 2 + \frac{4}{p+2}$ (Jiang-Lin, CAM 2004).
- $d_u \leq n - 2 + \frac{2}{p+1}$ (Dupaigne-Ponce-Porretta, JAM 2006).

② Finite energy solution:

- $d_u \leq n - 2 + \frac{4}{p+1}$ (Guo-Wei, CPAA 2008).
- $d_u \leq n - 2 + \frac{2}{p+1}$ (Dávila-Ponce, CRMAS 2008).

③ Stationary solution:

- $d_u \leq n - 2 + \frac{4}{p+1}$ (Guo-Wei, MM 2006).
- $d_u \leq n - 2$ (Dávila-Wang-Wei, AIHP 2016).

The best estimate for d_u is achieved for stationary solutions!

Remarks on Results by Dávila-Wang-Wei

Theorem (Dávila-Wang-Wei, AIHP 2016)

Assume that $u \in C_{\text{loc}}^{0, \frac{2}{p+1}}$ is a *stationary solution* of $\Delta u = u^{-p}$. Then $\{u = 0\}$ is a *relatively closed* set with $d_u \leq n - 2$. In particular, if $n = 2$, then $\{u = 0\}$ is *discrete*.

Some remarks are as follows.

- 1 The assumption of $\frac{2}{p+1}$ -Hölder continuity is *optimal* and corresponds to the $C_{\text{loc}}^{1,1}$ regularity in the *obstacle problem*.
- 2 It is an *a priori* result. It is still unknown if a stationary solution must be $\frac{2}{p+1}$ -Hölder continuous.
- 3 The result is *sharp*. If $n = 2$,

$$u(x) = u(|x|) := \left(\frac{2}{p+1} \right)^{-\frac{2}{p+1}} |x|^{\frac{2}{p+1}}$$

is a *stationary solution* for $\Delta u = u^{-p}$ and $\{u = 0\} = \{0\}$.

Motivation of Our Works

Question

Can we obtain further information about the stationary solutions of (SN)?

Before we present the main results, we introduce the concept of rectifiability. Rectifiable sets can be viewed as manifolds for analyst.

Definition (Rectifiability)

Let $N \in \mathbb{Z}_+$ and $k \in \mathbb{Z} \cap [1, N]$. We call a set $M \subset \mathbb{R}^N$ as k -rectifiable if

$$M \subset M_0 \cup \bigcup_{i \in \mathbb{Z}_+} f_i(\mathbb{R}^k),$$

where $\mathcal{H}^k(M_0) = 0$, and $f_i : \mathbb{R}^k \rightarrow \mathbb{R}^N$ is a Lipschitz map $\forall i \in \mathbb{Z}_+$.

Remark: Here, “Lipschitz” can be replaced by “ C^1 .”

Theorem (Wang-Zhang, arXiv: 2411.16048)

$\frac{1}{2} + \frac{1}{2p} < \frac{q}{n}$. $u \in C_{\text{loc}}^{0, \frac{2}{p+1}}(B_4)$ is a *stationary solution* of (SN) with $f \in L_{\text{loc}}^q(B_4)$, satisfying $\|u\|_{L^1(B_2)} + \|f\|_{L^q(B_2)} \leq \Lambda$. The following properties hold.

- ① $\exists \varepsilon, C = C(\Lambda, n, p, q) > 0$, s.t.

$$\mathcal{L}^n(B_r(\{u < \varepsilon r^{\frac{2}{p+1}}\} \cap B_1)) \leq Cr^2, \quad 0 < r < 1.$$

- ② If $f \in W_{\text{loc}}^{j-1, \infty}(B_4)$ with $j \in \mathbb{Z}_+$ and $\|f\|_{W^{j-1, \infty}(B_2)} \leq \Lambda'$, then

$$\sup \left\{ \lambda > 0 : \lambda^{\frac{2(p+1)}{j(p+1)-2}} \mathcal{L}^n(\{x \in B_1 : |D^j u(x)| > \lambda\}) \right\} \leq C',$$

where $C' = C'(\Lambda, \Lambda', j, n, p, q) > 0$.

- ③ $\{u = 0\}$ is $(n-2)$ -rectifiable, and for $n = 2$, $\{u = 0\}$ is a discrete set.

Some Remarks on Our Results

- ① We estimate the $(n-2)$ -dimensional Minkowski r -content for $\{u < \varepsilon r^{\frac{2}{p+1}}\}$.
In particular,

$$\dim_{\text{Min}}(\{u = 0\} \cap B_1) \leq n - 2.$$

- ② The $L^{\frac{2(p+1)}{j(p+1)-2}, \infty}$ and $(n-2)$ -rectifiability of $\{u = 0\}$ are both sharp.
- ③ By standard interpolation,

$$D^j u \in L^{\frac{2(p+1)}{j(p+1)-2}-}(B_1), \quad j \in \mathbb{Z}_+,$$

i.e. $\forall 0 < s < \frac{2(p+1)}{j(p+1)-2}, \exists C = C(\Lambda, \Lambda', j, n, p, q, s) > 0$, s.t.

$$\|D^j u\|_{L^s(B_1)} \leq C.$$

For $j = 1$, $u \in W^{1, \frac{2(p+1)}{p-1}}(B_1)$, improving the H^1 regularity.

- ④ In fact, any k -stratum of $\{u = 0\}$ is k -rectifiable with $k \in \mathbb{Z} \cap [0, n-2]$.
Here, the stratification is based on the tangent function.

- Sketch of the Proof

Terminologies of Harmonic Maps

$\Omega \subset \mathbb{R}^n$: bounded domain. $\mathcal{N} \hookrightarrow \mathbb{R}^d$ smooth, compact manifold, embedded into \mathbb{R}^d . **Harmonic map**: the **critical point** of the variational problem

$$\mathcal{E}(\Phi, \Omega) := \int_{\Omega} |\nabla \Phi|^2, \quad \Phi = (\Phi^1, \Phi^2, \dots, \Phi^d) \in H^1(\Omega, \mathcal{N}).$$

Definition (Local minimizer & Weakly harmonic map)

$\Phi \in H^1(\Omega, \mathcal{N})$ is a **local minimizer** if $\forall B_r(x) \subset\subset \Omega$, and $\Psi \in H^1(B_r(x), \mathcal{N})$ with $\Phi = \Psi$ on $\partial B_r(x)$,

$$\mathcal{E}(\Phi, B_r(x)) \leq \mathcal{E}(\Psi, B_r(x)).$$

Φ is a **weakly harmonic map** if $\forall \varphi = (\varphi^i)_{i=1}^d \in C_0^\infty(\Omega, \mathbb{R}^d)$,

$$\int_{\Omega} (\nabla \Phi \cdot \nabla \varphi - A(\Phi)(\nabla \Phi, \nabla \Phi) \cdot \varphi) = 0,$$

where $A(y)(\cdot, \cdot) : T\mathcal{N} \times T\mathcal{N} \rightarrow (T\mathcal{N})^\perp$ is the **second fundamental form** of \mathcal{N}

Definition (Stationary harmonic map)

$\Phi \in H^1(\Omega, \mathcal{N})$ is a **stationary harmonic map** if Φ is a **weakly harmonic map** and satisfies the **stationary condition**

$$\int_{\Omega} (|\nabla \Phi|^2 \operatorname{div} Y - 2DY(\nabla \Phi, \nabla \Phi)) = 0,$$

$$\forall Y \in C_0^\infty(\Omega, \mathbb{R}^n).$$

As given previously,

$$\text{Stationary condition} \Leftrightarrow \left. \frac{d}{dt} \right|_{t=0} \mathcal{E}(\Phi(\cdot + tY(\cdot)), \Omega) = 0.$$

It is obvious that

Local minimizer \Rightarrow Stationary harmonic map \Rightarrow Weakly harmonic map.

For a harmonic map $\Phi \in H^1(\Omega, \mathcal{N})$, the **singular set** is

$$S(\Phi) = \{x \in \Omega : \forall r > 0, \Phi \text{ is not continuous in } B_r(x)\}.$$

Results on $S(\Phi)$ for Harmonic Maps

Let $d_\Phi := \dim_{\mathcal{H}}(S(\Phi))$.

① Estimates of the Hausdorff dimension:

- **Local minimizer:** $d_\Phi \leq n - 3$ (Schoen and Uhlenbeck, JDG 1982).
- **Stationary harmonic map:** $d_\Phi \leq n - 2$ (Bethuel, MM 1993).

② Rectifiability:

- **Local minimizer:** For **real and analytic** \mathcal{N} , $S(\Phi)$ is $(n - 3)$ -rectifiable and the k -stratum is k -rectifiable (Simon, CVPDE 1995).
- **Stationary harmonic map:**
 - The **concentration set** is $(n - 2)$ -rectifiable (Lin, AM 1999).
 - For **merely smooth** \mathcal{N} , $S(\Phi)$ is $(n - 2)$ -rectifiable, and the k -stratum is k -rectifiable (Naber and Valtorta, AM 2017).

The results in (Dávila-Wang-Wei, AIHP 2016) follows from similar arguments in (Schoen and Uhlenbeck, JDG 1982), applying Federer's dimensional reduction!

Difficulties in the Proof of Rectifiability

Assumption (Simplified model)

$u \in C_{\text{loc}}^{0, \frac{2}{p+1}}(B_2)$ is a *stationary solution* of $\Delta u = u^{-p}$ in B_2 with $p > 1$.

For $B_r(x) \subset B_2$, the widely used *density* is

$$\theta(u; x, r) := r^{\frac{2(p-1)}{p+1}-n} \int_{B_r(x)} \left(\frac{|\nabla u|^2}{2} - \frac{u^{1-p}}{p-1} \right) - \frac{r^{-\frac{4}{p+1}-n}}{p+1} \int_{\partial B_r(x)} u^2.$$

Moreover, it satisfies the *monotonicity formula*

$$\frac{d}{dr} \theta(u; x, r) = r^{-\frac{4}{p+1}-n} \int_{\partial B_r(x)} \left| (y-x) \cdot \nabla u - \frac{2u}{p+1} \right|^2 d\mathcal{H}^{n-1}(y) \geq 0.$$

$$x \in \{u > 0\} \Leftrightarrow \lim_{r \rightarrow 0^+} \theta(u; x, r) = -\infty.$$

$\theta(u; x, r)$ can be negative!

Previous arguments in harmonic maps require the nonnegativity of the density!

Blow up Analysis I

Classical blow-ups. (Dávila-Wang-Wei, AIHP 2016) For $x \in B_2$,

$$u_{x,r}(y) := r^{-\frac{2}{p+1}} u(x + ry).$$

- ① If $x \in \{u = 0\}$, then $\exists r_i \rightarrow 0^+$, s.t.

$$u_{x,r_i} \rightarrow u_\infty \text{ strongly in } H_{\text{loc}}^1 \cap L_{\text{loc}}^\infty \cap L_{\text{loc}}^{-p},$$

where $\Delta u_\infty = u_\infty^{-p}$ is a **stationary solution**. Here we call u_∞ a **tangent function** of u at x .

- ② If $x \in \{u > 0\}$, then

$$u_{x,r} \rightarrow +\infty \text{ uniformly in any compact set, } r \rightarrow 0^+.$$

For $x \in \{u > 0\}$, the blow-ups do not have a limit!

Stratification I

Definition (k -symmetric function)

$k \in \mathbb{Z} \cap [0, n]$. $h \in C_{\text{loc}}^{0, \frac{2}{p+1}}(\mathbb{R}^n)$ is k -symmetric at $x \in \mathbb{R}^n$ wrt $V \subset \mathbb{R}^n$ with $\dim V = k$ if h is $\frac{2}{p+1}$ -homogeneous at x and invariant with respect to V . If $x = 0$, we call that h is k -symmetric.

Definition (Stratification I)

$\forall k \in \mathbb{Z} \cap [0, n-1]$, define the k -stratum of u by

$$S_{(1)}^k(u) := \{x \in \{u = 0\} : \text{no tangent function } v \text{ of } u \text{ at } x \text{ is } (k+1)\text{-symmetric}\}.$$

As a result,

$$S_{(1)}^0(u) \subset S_{(1)}^1(u) \subset S_{(1)}^2(u) \subset \dots \subset S_{(1)}^{n-1}(u) = \{u = 0\}.$$

Indeed,

$$S_{(1)}^0(u) \subset S_{(1)}^1(u) \subset S_{(1)}^2(u) \subset \dots \subset S_{(1)}^{n-2}(u) = S_{(1)}^{n-1}(u) = \{u = 0\}.$$

Rectifiability: Idea

After (Naber and Valtorta, AM 2017), in (A. Naber and D. Valtorta, MZ 2018), there are simplified arguments only requiring the **boundedness** of the density.

For u satisfying the assumption of the simplified model,

$\theta_r(u; x, r)$ is locally bounded in $\{u = 0\}$.

Idea: Restrict the analysis on the rupture set and apply methods by Naber and Valtorta in MZ 2018.

Rectifiability: Modified Densities

Following (Hirsch, Stuvard, and Valtorta, TAMS 2019), we also modify the density $\theta_r(u; x, r)$ by

$$\vartheta(u; x, r) = r^{\frac{2(p-1)}{p+1}-n} \int_{\mathbb{R}^n} \left(\frac{|\nabla u|^2}{2} - \frac{u^{1-p}}{p-1} \right) \phi_{x,r} + \frac{2r^{-\frac{4}{p+1}-n}}{p+1} \int_{\partial B_r(x)} u^2 \dot{\phi}_{x,r}.$$

Definition

Let $\phi : [0, +\infty) \rightarrow [0, +\infty)$.

- $\text{supp } \phi \subset [0, 10)$ and ϕ is **decreasing**.
- $\phi(t) \geq 0$, and $|\phi'(t)| \leq 100$, $\forall t \in [0, +\infty)$.
- $-2 \leq \phi'(t) \leq -1$, $\forall t \in [0, 8]$.

For $x \in \mathbb{R}^n$,

$$\phi_{x,r}(y) := \phi\left(\frac{|y-x|^2}{r^2}\right), \quad \dot{\phi}_{x,r}(y) := \phi'\left(\frac{|y-x|^2}{r^2}\right).$$

Such a “modification” can avoid the application of **unique continuation**.

Difficulties in the Proof of Regularity Improvement

To **enhance the regularity**, we have to obtain.

$$\mathcal{L}^n(B_r(\{u < \varepsilon r^{\frac{2}{p+1}}\} \cap B_1)) \leq C \left([u]_{C^{0, \frac{2}{p+1}}}, n, p \right) r^2.$$

It is easy to show

$$\mathcal{L}^n(B_r(\{u = 0\} \cap B_1)) \leq C \left([u]_{C^{0, \frac{2}{p+1}}}, n, p \right) r^2.$$

Difficulty: The density does not have a **uniform bound** in $\{u < \varepsilon r^{\frac{2}{p+1}}\}$.

For u and $B_r(x) \subset \{u > 0\}$, we have the **nondegeneracy**

$$\sup_{B_r(x)} u \geq C' \left([u]_{C^{0, \frac{2}{p+1}}}, n, p \right) r^{\frac{2}{p+1}}.$$

We need the one with “inf” replacing “sup”!

Blow up Analysis II and Stratification II

Refined blow-ups. For $x \in B_2$, let

$$\tilde{u}_{x,r}(y) := r^{-\frac{2}{p+1}} (u(x + ry) - u(x)).$$

- ① If $x \in \{u = 0\}$, then $\exists r_i \rightarrow 0^+$, s.t.

$$\tilde{u}_{x,r_i} \rightarrow u_\infty \text{ strongly in } H_{\text{loc}}^1 \cap L_{\text{loc}}^\infty \cap L_{\text{loc}}^{-p},$$

where $\Delta u_\infty = u_\infty^{-p}$ is a stationary solution.

- ② If $x \in \{u > 0\}$, then

$$\tilde{u}_{x,r} \rightarrow 0 \text{ strongly in } H_{\text{loc}}^1 \cap L_{\text{loc}}^\infty, \quad r \rightarrow 0^+.$$

Definition (Stratification II)

$\forall k \in \mathbb{Z} \cap [0, n-1]$, define the k -stratum of u by

$$S_{(\text{II})}^k(u) := \{x \in B_2 : \text{no tangent function } v \text{ of } u \text{ at } x \text{ is } (k+1)\text{-symmetric}\}.$$

$$S_{(\text{II})}^0(u) \subset S_{(\text{II})}^1(u) \subset S_{(\text{II})}^2(u) \subset \dots \subset S_{(\text{II})}^{n-1}(u) = B_2.$$

Alternative Result: Intuition

We will deal with points in B_2 through an **alternative result**.

① $0 \leq u(x) \ll r^{\frac{2}{p+1}}:$

The behavior of u within $B_r(x)$ is like the case that $u(x) = 0$. Thus, we apply methods in line with (Naber and Valtorta, MZ 18).

② $u(x) \gtrsim r^{\frac{2}{p+1}}:$

We use the **standard regularity theory** for elliptic equations to find a small ball $B_{\delta r}(x)$ with $\delta \ll 1$ s.t. u exhibits nice properties.

Quantitative Stratification: Definitions

Definition (Quantitative symmetry)

$\varepsilon > 0$, and $k \in \mathbb{Z} \cap [0, n]$. u is (k, ε) -symmetric in $B_r(x) \subset\subset B_2$, if there is a k -symmetric function $h \in C_{\text{loc}}^{0, \frac{2}{p+1}}(\mathbb{R}^n)$ s.t. $\|\tilde{u}_{x,r} - h\|_{L^\infty(B_1)} < \varepsilon$.

Definition (Quantitative stratification)

$\varepsilon > 0$, $k \in \mathbb{Z} \cap [0, n-1]$, and $0 < r < 1$, the k -th (ε, r) -stratification of u , denoted by $S_{\varepsilon,r}^k(u)$, is

$$S_{\varepsilon,r}^k(u) := \{x \in B_1 : u \text{ is not } (k+1, \varepsilon)\text{-symmetric in } B_s(x) \text{ for any } r \leq s < 1\}.$$

In fact,

$$S_{(II)}^k(u) \cap B_1 = \bigcup_{\varepsilon > 0} S_{\varepsilon}^k(u) = \bigcup_{\varepsilon > 0} \bigcap_{0 < r < 1} S_{\varepsilon,r}^k(u).$$

Quantitative Stratification: Main Theorems

Theorem (Main)

$\varepsilon > 0$ and $k \in \mathbb{Z} \cap [0, n-2]$. Assume that $[u]_{C^{0, \frac{2}{p+1}}(\overline{B_2})} \leq \Lambda$. If $0 < r < 1$, then

$$\mathcal{L}^n(B_r(S_{\varepsilon, r}^k(u))) \leq C(\varepsilon, \Lambda, n, p)r^{n-k}.$$

- 1 This theorem is **sharp**, giving paralleled results as harmonic maps.
- 2 The result implies the **Ahlfors regularity** of $S_{\varepsilon}^k(u)$ and then the **rectifiability**.
- 3 The proof of

$$\mathcal{L}^n(B_r(S_{\varepsilon, r}^k(u) \cap \{u = 0\})) \leq C(\varepsilon, \Lambda, n, p)r^{n-k}$$

is much easier and enough to obtain the **rectifiability of $S^k(u)$** . However, it is not sufficient to obtain the **improvement of regularity**.

Quantitative Stratification: Lemmas I

By simple **compactness arguments**, we have:

Lemma

$$[u]_{C^{0, \frac{2}{p+1}}(\overline{B_2})} \leq \Lambda. \quad \exists \varepsilon = \varepsilon(\Lambda, n, p) > 0 \text{ s.t. } \forall 0 < r < 1$$

$$\{x \in B_1 : u(x) < \varepsilon r^{\frac{2}{p+1}}\} \subset S_{\varepsilon, r}^{n-2}(u).$$

By the estimate of $S_{\varepsilon, r}^k(u)$, this lemma implies that

$$\begin{aligned} \mathcal{L}^n(\{x \in B_1 : u(x) < \varepsilon r^{\frac{2}{p+1}}\}) &\leq \mathcal{L}^n(B_r(S_{\varepsilon, r}^{n-2}(u))) \\ &\leq C(\varepsilon, \Lambda, n, p) r^{n-(n-2)} \\ &\leq C(\varepsilon, \Lambda, n, p) r^2. \end{aligned}$$

Quantitative Stratification: Lemma II

The **key step** in obtaining the main theorem is the following lemma. The rest of the proof is an application of arguments by Naber and Valtorta through lengthy and tricky **covering methods**.

Lemma

$k \in \mathbb{Z} \cap [0, n-2]$, $0 < s \leq 1$, and $x \in \mathbb{R}^n$. $[u]_{C^{0, \frac{2}{p+1}}(\bar{B}_{15s}(x))} \leq \Lambda$. $\forall \varepsilon > 0$, there exist $\delta, \delta' = \delta, \delta'(\varepsilon, \Lambda, n, p) > 0$ s.t. if

$$\inf_{V \subset \mathbb{R}^n, \dim V = k+1} \left(s^{\frac{2(p-1)}{p+1} - n} \int_{B_s(x)} |V \cdot \nabla u|^2 \right) < \delta,$$

then $r_x \in [\delta's, s]$ s.t. u is $(k+1, \varepsilon)$ -symmetric in $B_{r_x}(x)$.

- 1 For **harmonic maps**, the proof of a similar result is simple.
- 2 If we use $u_{x,r}$ to define **quantitative stratification**, we cannot obtain such a result without assuming that $u(x) = 0$.

Quantitative Stratification: Alternative Lemma

Lemma (Alternative lemma)

$k \in \mathbb{Z} \cap [0, n-2]$, $0 < r \leq 1$, and $x \in \mathbb{R}^n$. $[u]_{C^{0, \frac{2}{p+1}}(\bar{B}_{15r}(x))} \leq \Lambda$. $\forall \varepsilon > 0$, there are $\delta = \delta(\varepsilon, \Lambda, n, p) > 0$ and $\gamma = \gamma(n, p) > 0$ s.t. if

$$\inf_{V \subset \mathbb{R}^n, \dim V = k+1} \left(r^{\frac{2(p-1)}{p+1} - n} \int_{B_r(x)} |V \cdot \nabla u|^2 \right) < \delta,$$

then either $u(x) \geq \delta^\gamma r^{\frac{2}{p+1}}$, or $\exists r_x \in [\delta^\gamma r, r]$ s.t.

u is $(k+1, \varepsilon)$ -symmetric in $B_{r_x}(x)$.

- 1 The idea of the proof is to first let $\sigma > 0$ and assume that $u(x) < \sigma r^{\frac{2}{p+1}}$. By compactness arguments, if $\sigma \ll 1$, the result follows.
- 2 By this lemma, if $u(x) \geq \delta^\gamma r^{\frac{2}{p+1}}$, we can use the regularity theory of elliptic equations to obtain that in a smaller ball with radius which is comparable to r_x , where u is $(k+1, \varepsilon)$ -symmetric in it.

Thank you for listening!
